**ABSTRACT**

Hexane extracts of oil from brown and yellow Cyperus esculentus Lativum tubers was physico-chemically analyzed for quality evaluation and the following results were obtained: Acid values; 0.41±0.015 mgKOH/g and 0.48±0.014 mgKOH/g, Free fatty acids;77.00±1.0(% oleic acid) and 72.67 ±1.528(% oleic acid); Iodine values; 71.00±0.414gI₂/100g and 76.67±2.517. Peroxide values; 3.80± 0.1 meq H₂O₂ and 4.10±0.153 meq H₂O₂. Saponification values; 193.33±2.121 mgKOH/g and 188.33±0.707 mgKOH/g respectively. The oil yield was 26.15±3.142 % and 27.50± 5.721 respectively, while the colour was physically observed to be brown for the smaller variety (brown Cyperus esculentus tuber) and yellow for the larger variety (yellow Cyperus esculentus tuber). Justification of the cosmetic potential of the two varieties of Cyperus esculentus tubers was expatiated.

Introduction

Cyperus esculentus Lativum is an underutilized crop of the family cyperaceae which produces rhizomes from the base and tubers that are somewhat spherical. The tubers produces high quality oil about 25.5% of its content which was implicated as lauric graded oil, non acidic stable and very low unsaturated (Adejuyitan, 2011 ). Tigernut belongs to the sub-family Escripoidea, genus cyperus, specie esculentus, and botanical variety Lativum. Thus, its botanical name Cyperus esculentus Lativum (Mason, 2005). It has many other names like; Chufa, Zulu nuts, yellow nut grass, and ground almond, edible rush and rush nuts (Jansen, 1971). In Nigeria, some of its native names include ‘Aya’ in Hausa, ‘Imumu’ in Yoruba, ‘Ofio’ or ‘aki-hausa’ in Igbo(Osagie and Eka, 1998). The derivatives and benefits of Cyperus esculentus Lativum as a plant was reported(Bamishaiye and Bamishaiye, 2011). This research is aimed at quality evaluation of oil from Brown and Yellow Cyperus esculentus Tubers and justify their industrial potential for cosmetic preparations.

Materials And Methods

Sample preparation

The Cyperus esculentus L .tubers which was procured from local tiger nut traders at Tawa market, Niger Republic were air-dried in the laboratory at room temperature, for a period of one week, and was then ground, using manual pestle and mortar. The dry powdered sample was then kept at room temperature in the laboratory for extraction.

Oil extraction

The extraction of oil from the tubers was carried out in a soxhlet apparatus using analytical grade hexane (n. hexane) as refluxing or extracting solvent for the work. At the completion of the extraction process the oil was recovered from the mixture by evaporating the residual extracting solvent in an oven set at 50°C and stored in the bottle. This process was repeated until a substantial quantity of oil was achieved. Each batch of extraction lasted for about 5 hours on the average (Okolie et al., 2012).

Determination of Percentage Yield.

The oil obtained from the extraction was transferred into a measuring cylinder which was placed over water bath for 30 min at 70°C so as to ensure complete evaporation of solvent and volume of the oil was recorded (Warra et al., 2011a).
Oil content (%) = \( \times \) 100

**Determination of Colour**

The colour of the oil samples was determined by observation using several independent competent individuals. Oil colour was correlated using colour charts (Okolie et al., 2012).

**Physicochemical analysis**

**Determination of Saponification Value** (AOAC,1998). 2g of the oil sample was added to a flask with 30 cm³ ethalonic KOH and the flask was then attached to a condenser for 30 min to ensure the sample was fully dissolved. After the sample has cooled, 1 cm³ of phenolphthalein was added and titrated with 0.2 M HCL until a pink end point has reached. The sample analysis was performed using blank. Blank was also prepared using the same reagents as the sample without the oil in it. Saponification value was calculated from the equation below:

\[ SV = \frac{(S-B) \times M \times 56.1}{\text{Sample weight (g)}} \]

Where \( S \) = sample titre value, \( B \) = blank titre value, \( M \) = molarity of the HCL, 56.1= molecular weight of KOH.

**Determination of Acid Value** (AOAC,1990). The acid value of the sample oil was determined by dissolving about 5.0-5.5g of the sample oil in a hot mixture of 25ml diethyl ether and 25ml 95% v/v ethyl alcohol. The hot solution was neutralized with 0.1 M NaOH using phenolphthalein as indicator.

\[ A.V = \frac{MC \times TV}{W} \]

Where \( M \) = molar mass of KOH (56.1), \( C \) = concentration of KOH (0.1M), \( TV \) = titre value, \( W \) = weight of oil sample

**Determination of Iodine Value** (AOAC,1990). About 0.26g of the sample oil was weighed into a glass stoppered flask and dissolved in 10ml cyclohexane. 20ml of Wij’s solution was added; the flask was stoppered and allowed to stand for 30 minutes in the dark at 25°C after which 20ml of 10% KI solution was added. The mixture was titrated with 0.1M Na₂S₂O₃ using starch as indicator. A blank was carried out and the iodine value was calculated.

\[ \text{Iodine value} = \frac{12.69 \times C(\text{V1} - \text{V2})}{W} \]

Where \( C \) = concentration of sodium thiosulphate solution, \( \text{V1} \) = volume (ml) of sodium thiosulphate solution used in blank, \( \text{V2} \) = volume (ml) of sodium thiosulphate solution used in the determination, \( W \) = weight of the sample.

**Determination of Free Fatty Acid** (AOAC,1998). 0.5g of sample oil was boiled with 5cm³ of ethanol allowed to cool and 2 drops of phenolphthalein indicator was added, then titrated with 0.1N NaOH until pink color disappear. Free fatty acid can be calculated using the expression below.

\[ \text{FFA} = \frac{VX Na \times F}{Ws \times X} \times 100 \]

Where, \( V \) = titre value, \( Na \) = normality of acid, \( F \) = equivalent weight of free fatty acid, \( Ws \) = weight of sample

**Determination of Peroxide Value** (AOAC,1990). 1g of the sample was weighted into a clean dry boiling tube and 1g powdered potassium iodide (KI) plus 20ml of the solvent mixture (2 volume glacial acetic acid and 1 vol. chloroform) was added. The mixture was boiled vigorously for 1 minute using boiling water as the heating source. Then the boiled mixture was transferred quickly into a flask containing 20ml of 5% KI and the tube was washed twice with 25ml of distilled water into the flask. The content of the flask was titrated with 0.002M sodium thiosulphate (Na₂S₂O₃) solution using starch as indicator. A blank was determined at the same time and condition. The peroxide value of the sample oil was calculated.

**Results**

Discussions

The oil yield for the brown and yellow Cyperus esculentus tubers oil were 26.15±3.142% and 27.50±5.721% respectively. The values despite being lower than 36.75 0.50% reported for Nicotiana tabacum seed oil and recommended production of hair shampoo (Chinweuba, 2013) were higher than 21.2% and 23.9% optimum yield for pericarp (peels) of avocado apples oextracted by indirect and direct extraction using n–hexane respectively, which was recommended for as a potential substitute for most oils used for cosmetics and health care production (Adama and Edoga, 011).

From the exploited parameters, Acid values of 0.41±0.015 mgKOH/g and 0.48±0.014 mgKOH/g were obtained for brown and yellow Cyperus esculentus tubers oil, the values were lower than the acid value of 0.81 ± 0.01 for cotton seed oil (Warra et al., 2011b) 10.3mgKOH/g for shea nut butter (Warra et al., 2009) and 2.34 ± 0.19 mg KOH/g for Luffa cylindrica (Linn.) seed oil (Gafar et al., 84) reported in literature and recommended for soap making, but relatively closer to 0.421 mgKOH/g reported for Adansonia Digitata seed oil recommended for use as an ingredient in tooth paste (Chindo et al., 2010)

Free fatty acid (% oleic acid) of 77.00±1.0 and 72.67 ±1.528 (% oleic acid) were obtained the brown and yellow Cyperus esculentus tubers oil which were higher than 37.96% reported for Nigerian rubber seed oil (Ebewele et al., 2010) far higher than free fatty acid (oleic) obtained for bread-fruit oil (2.86%) and breadnut oil, 1.89% (Nwingu et al., 2001).Oils with highly acidic free fatty acid indicates unsuitability for edible purpose except for technical purposes (Ebewele et al., 2010)

Iodine values obtained were 71.00±0.414 gl/100g and 76.67±2.517 gl/100g respectively the values are lower than Iodine value of 119.78 ± 0.81g 12/100g reported for cotton seed oil (Warra et al., 2011b) but higher than 30.33 ± 2.40g 1/100g for Sponge Gourd (Luffa cylindrica) oil ( Gafar et al., 2012) recommended for in soap and other cosmetics. Iodine value is an indication of double bonding in the molecular structure and influences the long term stability properties of oil which is important for storage.

Peroxide values of 3.80± 0.1 meq H2O2 and 4.10±0.153 meq H2O2 were obtained which are lower than 6.322mgO2/kg reported for Helianthus annus L. seed oil (Aboke et al, 2012) and 11.75 reported for fluted pumpkin (Eddy et al., 2012). The low peroxide values of the oil samples is an indication that the oils are stable and may not be susceptible to oxidative rancidity since they are produced from fresh seeds (Eddy et al., 2012).

Saponification values 193.33±2.121 mgKOH/g and 188.33±0.707 mgKOH/g were obtained respectively which are lower than the saponification values of 199.42 ± 0.53 mgKOH/g for cotton seed oil (Warra et al., 2011b) and 213mgKOH/g for neem seed oil (Warra et al., 2011c) but higher than 116.88 ± 0.97 mg KOH/g for Cucumis melo Linn Seed oil (Gafar, et al., 2013) reported and recommended for cosmetic applications.

Conclusion

The oil extracts showed good physicochemical properties and could be useful for soap, toothpaste and other cosmetic applications.
